

Q8. The Stack-Structured Operation

An arithmetic operation is formatted as (operand, operand, operator) where the operator could be +, -, *, or / and the operands could be integers other than 0. For examples, (2, 3, *) = $2 * 3 = 6$ and (-8, 2, /) = $-8 / 2 = -4$. Write a program that can read such an operation and output the result.

The Input

The first line is a positive integer indicating how many lines (operations) are following. The following lines can be either a correctly formatted operation (maybe a nested one) or a wrong one

The Output

According to the format described in the problem, calculate the operation result and print it if the format is correct. Otherwise, just print "Invalid Input!" instead.

Sample Input

```
2
((3,5,*),((2,4,*),6,-),+)
((3,0,*),((2,4.5,*),6,-),+)
```

Sample Output

```
17
Invalid Input!
```
