

Detection for a Specific-patterned String

The Problem

Write a program to detect a string of `XYX` pattern (length 3, the third character must be the same as the first one, where `X` and `Y` could be any English letter) within a long string (length `n`, $3 < n < 1000$). The input consists of two strings separated by a space character, where the first string is the target string and the second one is the searching range. The output is the number of successful detections. Notice that overlapped patterns are allowed and should be counted individually. For example, target string `LBL` appears 3 times in range string `XLBLBLBLY` (not just twice).

The Input

Two or multiple strings separated by a space character. If the first one is not a `XYX` patterned string of length-3, or there are more strings than 2, just output "Wrong format" .

The Output

The number of successful detections in the searching range.

Sample Input

```
LPL BEGINHELLPPLPLXYXYXYPLPLPLPLLLPLEND
GGG BEGINGGYGGGGGHKGGGGGGGGYGEND
LKK BEGINLKKLKKKLKEND
LKLK BEGINLKKLKKKLKEND
GGGBEGINGGYGGGGGHKGGGGGGGGYGEND
GGG, BEGINGGYGGGGGHKGGGGGGGGYGEND
```

Sample Output

```
6
9
Wrong format
Wrong format
Wrong format
```

Wrong format
